Instructions

Lab 7: The Rotation Curve and Mass of the Galaxy: Dark Matter

Read the lab before attending lab. You might find it easier to navigate if you expand only one or two sections at a time.

The following summary video is available to you in case you miss lab or want to review it when completing the lab:

**Rotation Curve and Mass of the Galaxy** (28:36)

You are permitted 100 submissions per question. Use some of these to save your work.

If you do not save your work periodically, you risk losing it when WebAssign times you out. WebAssign does this after a few hours for security reasons.

Do not open multiple copies of this assignment, or multiple WebAssign assignments, or you risk losing your answers upon saving or submitting.

Enter all calculated values to at least two significant digits.

Do not add units when entering numerical responses. WebAssign will not accept your response.

Do not use special characters when naming files. WebAssign will not accept your file.

Follow Skynet on [Facebook](https://www.facebook.com) and [Twitter](https://twitter.com)!

**LAB 7 — THE ROTATION CURVE AND MASS OF THE GALAXY: DARK MATTER**

**GOALS**

In this lab, you will:
- Measure the speeds at which matter orbits our galaxy.
- Measure the rotation curve of our galaxy, and use it to determine if our galaxy's mass is concentrated at its center or spread throughout its disk.
- Measure the mass of our galaxy within different radii from its center, and use this information to determine if our galaxy is composed primarily of visible matter or of a combination of visible and dark matter.

**EQUIPMENT**

Computer with internet connection

**BACKGROUND: A. DOPPLER EFFECT**

Consider a source of light. If the source is stationary with respect to observers, the observed wavelength $\lambda_{\text{obs}}$ will be the same as the emitted wavelength $\lambda_{\text{em}}$. 
But if the source is moving with respect to observers, the waves will be compressed in the direction of motion, resulting in a shorter observed wavelength, or bluer light. Similarly, the waves will be stretched out in the opposite direction, resulting in longer observed wavelengths, or redder light.

Mathematically, if the source is moving toward the observer, the observed wavelength $\lambda_{\text{obs}}$ will be shorter than the emitted wavelength $\lambda_{\text{em}}$ by $\Delta\lambda$.

$$\lambda_{\text{obs}} = \lambda_{\text{em}} - \Delta\lambda$$

And if the source is moving away from the observer, the observed wavelength $\lambda_{\text{obs}}$ will be longer than the emitted wavelength $\lambda_{\text{em}}$ by $\Delta\lambda$.

$$\lambda_{\text{obs}} = \lambda_{\text{em}} + \Delta\lambda$$

In both cases, the change in wavelength $\Delta\lambda$ is given by:

$$\Delta\lambda = \lambda_{\text{em}} \times \Delta V/c$$

where $\Delta V_{\text{total}}$ is the source's speed relative to the observer and $\Delta V$ is the component of $\Delta V_{\text{total}}$ along the line of sight between the source and the observer.
If we want to measure Doppler shifts of matter orbiting our galaxy, we must look in the plane of our galaxy. However, dust blocks visible light in the plane of our galaxy. Consequently, we must observe at a different wavelength.

Cold hydrogen gas consists of a proton and an electron in the ground state. Because both particles are charged and spinning, they have magnetic fields along their rotation axes. Like bar magnets, it takes more energy to keep them together if their magnetic fields are aligned than if they are oppositely aligned. If a hydrogen atom is in the aligned state, after an average timescale of 11 million years, it will randomly de-excite to the oppositely aligned state, releasing the small difference in energy as a 21 cm photon.

Although this is a rare occurrence, cold hydrogen gas is so abundant in our galaxy that this results in a strong signal, making the plane of our galaxy glow at this radio wavelength.

Consider taking a radio spectrum of the center of our galaxy.
What would it look like around 21 cm?

To figure this out, consider the following figure, which shows what our galaxy might look like face on. Our location is marked by the yellow dot near the bottom of the figure. The dotted line marks the line of sight from us to (and through) the center of our galaxy.

Notice that the line of sight intersects spiral arms of our galaxy, and hence cold hydrogen gas, at many points. However, at all of these points, the gas is orbiting our galaxy neither toward us nor away from us, but perpendicular to the line of sight. Consequently, the 21-cm light that this gas is emitting is neither blueshifted nor redshifted. The radio spectrum should simply consist of a single emission line with $\lambda_{\text{obs}} = \lambda_{\text{em}}$. 
Now consider taking a radio spectrum not of the center of our galaxy, but at a greater Galactic longitude (see Lab 6).

In this case, the line of sight intersects spiral arms, and hence cold hydrogen gas, at different points. Furthermore, these regions of gas are orbiting our galaxy not perpendicular to the line of sight, but each with a different component of its speed along the line of sight.
Consequently, the 21-cm light that these regions of gas are emitting should be Doppler shifted each by a different amount, resulting in a more complicated spectrum.

However, one of these regions of gas is special, because its motion is neither to the left nor to the right of the line of sight, but along the line of sight. Consequently, the 21-cm light that this region of gas is emitting should be more redshifted than that of any other region along this line of sight. This most-redshifted emission is marked by the red arrow in the above spectrum.

**BACKGROUND: C. ROTATION CURVE - 2. Measuring Radial Distances and Orbital Speeds**

The most-redshifted region of gas along any line of sight is special because both (1) its distance from the center of our galaxy $R$ and (2) its orbital speed around our galaxy $V$ can be easily calculated.
By calculating $R$ and $V$ for many lines of sight (i.e., for many Galactic longitudes), we can determine how the speed at which our galaxy rotates changes with distance from its center. This is called our galaxy’s rotation curve.

With our galaxy's rotation curve, we can then determine how much mass must be present within any radius $R$ to make our galaxy rotate at speed $V$ at this radius. I.e., we can "weigh" our galaxy out to any radius $R$!

1. Measuring Radial Distances

First, consider a single line of sight. The most-redshifted region's distance from the center of our galaxy $R$ can be calculated from (1) our distance from the center of our galaxy $R_{\text{sun}} = 8.1$ kpc, which we measured in Lab 6, and (2) the Galactic longitude $l$ at which the spectrum was taken.

$$R = R_{\text{sun}} \times \sin(l)$$

Note: When using this equation, if using a calculator, it must be in degrees mode; if using a spreadsheet, you must first convert $l$ from degrees to radians.

2. Measuring Orbital Speeds

The most-redshifted region's orbital speed around our galaxy is the same as the component of its speed along the line of sight $V$. The difference between $V$ and the component of our speed along the line of sight is given by the Doppler effect equation from Section A, here solved for $\Delta V$:

$$\Delta V = c \times \Delta \lambda_{\text{em}}$$

where

$$\Delta \lambda = \lambda_{\text{obs}} - \lambda_{\text{em}}$$

and $\lambda_{\text{obs}}$ is the wavelength of the most-redshifted component of the spectrum (see figure below) and $\lambda_{\text{em}} = 21.1061$ cm is the precise wavelength at which cold hydrogen gas emits.

Note: The most-redshifted component is not necessarily the brightest component; it is the component most shifted to the right.

The component of our speed along the line of sight can be calculated from (1) our orbital speed around our galaxy $V_{\text{sun}} = 220$ km/s, which has been measured with respect to other galaxies in all directions around us, and (2) the Galactic longitude $l$ at which the spectrum was
Consequently, the most-redshifted region's orbital speed around our galaxy is given by:

\[ V = \Delta V + [V_{\text{sun}} \times \sin(\iota)] \]

*Note: When using this equation, if using a calculator, it must be in degrees mode; if using a spreadsheet, you must first convert \( \iota \) from degrees to radians.*

By taking spectra at many Galactic longitudes (Section A of the procedure) and calculating \( R \) and \( V \) of the most-redshifted region of gas from each spectrum (Section B of the procedure), you will measure how the speed at which our galaxy rotates changes with distance from its center: our galaxy's rotation curve.

**BACKGROUND: D. RADIAL MASS DISTRIBUTION**

Consider Earth orbiting the sun. It is currently at distance \( R \) and moving at speed \( V \). If the sun suddenly had no mass, Earth would continue along its current trajectory, leaving the sun. If the sun suddenly had infinite mass, it would deflect Earth's trajectory into the sun. Consequently, the sun must have just the right amount of mass to constantly deflect Earth's trajectory into its near-circular orbit.

The amount of mass required to keep an object that is moving at speed \( V \) in a circular orbit of radius \( R \) is:

\[ M(<R) = \frac{V^2 R}{G} \]

where \( M(<R) \) is the total mass within radius \( R \). In the case of the solar system, nearly all of the mass is concentrated at the center, in the sun. Hence, \( M(<R) \approx M_{\text{sun}} \) for any \( R \). Solving for \( V \) yields:

\[ V = \left[ \frac{G M_{\text{sun}}}{R} \right]^{1/2} \]

Consequently, \( V \) decreases as \( R \) increases. E.g., Mercury moves quickly but Neptune moves slowly. This is called a *Keplerian rotation curve* and is depicted as curve A below.
Now consider galaxies. If most of the mass is concentrated at or near the center, galaxies should also have Keplerian rotation curves. But if the mass is spread throughout the disk, $M(<R)$ will increase with $R$, in which case:

$$V = \left( \frac{GM(<R)}{R} \right)^{1/2}.$$

If $M(<R)$ increases in proportion to $R$, the $R$’s cancel out and $V$ is approximately constant. This is called a flat rotation curve and is depicted as curve B above.

By measuring our galaxy’s rotation curve, you can determine whether its mass is concentrated at or near its center or is spread throughout its disk. You can also use the first equation of this section to calculate how much mass must be contained within any radius $M(<R)$ to make the matter at that radius orbit in a circular (or near-circular) orbit. I.e., you can "weigh" our galaxy out to any radius $R$!

**PROCEDURE: A. RADIO SKYNET**

Funded by the American Recovery and Reinvestment Act through the National Science Foundation, Skynet is expanding to control not only visible-light telescopes like PROMPT, but also near-infrared and radio telescopes. In collaboration with the National Radio Astronomy Observatory (NRAO) in Green Bank, WV, our first radio telescope will be their 20-meter diameter telescope.

Twice the diameter of the world's largest visible-light telescope, this telescope, once refurbished, will be available for use through Skynet's web page and will be as easy to use as Skynet's visible-light telescopes. Furthermore, one of its capabilities will be 21-cm spectroscopy.

However, this project has just gotten underway. Until then, we will use radio spectra that students have acquired with NRAO-Green Bank's 40-foot (12-meter) diameter telescope.
Each summer, we take 15 students from across the country on a 1-week trip to NRAO-Green Bank, where they use this telescope and learn radio astronomy. If interested in applying, you can find more information on this website. Their spectra are linked in Table 1 of Section B.

Although small for a radio telescope, NRAO-Green Bank’s 40-foot diameter telescope has a nice 21-cm spectrograph. It was the 21-cm spectrograph of NRAO-Green Bank’s 300-foot (91-meter) diameter telescope before it collapsed in 1988.

**PROCEDURE: B. ROTATION CURVE**

Use the radio spectra obtained with NRAO-Green Bank’s 40-foot diameter radio telescope to measure the rotation curve of our galaxy:

- For each Galactic longitude in Column 1 of Data Table 1 below, click on the link to the corresponding radio spectrum and estimate $\lambda_{\text{obs}}$ of the most-redshifted region. Record this value to the nearest 0.0005 cm in Column 2.
- Using equations from Background Section C.2, calculate $\Delta V$. Use $\lambda_{\text{em}} = 21.1061$ cm and $c = 3.00 \times 10^5$ km/s. Note: $\Delta V$ can be negative (these are blueshifts). Record this value to the nearest 1 km/s in Column 3.
- Calculate the component of our speed along each line of sight $V_{\text{sun}} \times \sin(l)$. Use $V_{\text{sun}} = 220$ km/s. Note: If using a calculator, it must be in degrees mode; if using a spreadsheet, you must first convert from degrees to radians. Record this value to the nearest 1 km/s in Column 4.
- Using equations from Background Section C.2, calculate $R$. Use $R_{\text{sun}} = 8.1$ kpc. Note: If using a calculator, it must be in degrees.
mode; if using a spreadsheet, you must first convert $\ell$ from degrees to radians. Record this value to the nearest 0.01 kpc in Column 6.

**Question:** Sign your name to attest to the fact that you collected these data yourself.

**Question:** Present your calculation for $\Delta V$ for the $\ell = 84^\circ$ line of sight. (3 points)

**Question:** Present your calculation for $V_{\text{sun}} \times \sin(\ell)$ for the $\ell = 84^\circ$ line of sight. (2 points)

**Question:** Present your calculation for $V$ for the $\ell = 84^\circ$ line of sight. (3 points)

**Question:** Present your calculation for \( R \) for the \( \ell = 84^\circ \) line of sight. (3 points)

Go to this [website](https://example.com).

Make a graph of \( V \) (on the \( Y \) axis) vs. \( R \) (on the \( X \) axis). Save your final graph as a png file.

**Question:** Upload your final png graph. (Submit a file with a maximum size of 1 MB. 5 points)

No file chosen

**Question:** Is our galaxy's rotation curve more consistent with a Keplerian or a flat rotation curve? (2 points)

- Keplerian
- Flat

**Question:** Is our galaxy's mass concentrated at/near its center or spread throughout its disk? (2 points)

- Concentrated at/near center
- Spread throughout disk

**Question:** Discuss significant sources of error. (2 points)

**PROCEDURE: C. ENCLOSED MASS**

For each radius \( R \) in Data Table 1, use the first equation from Background Section D to calculate the mass enclosed within this radius \( M(<R) \) in billions of solar masses \( (GM_{\text{sun}}) \). Use \( V \) in km/s, \( R \) in kpc, and \( G = 4302 \text{ km/s}^2 \times \text{kpc}/(GM_{\text{sun}}) \). Record this value to the nearest 0.1 billion solar masses in Data Table 2 below.

**Data Table 2: Enclosed Mass (5.1 points)**

<table>
<thead>

Go to this [website](#).

Using the radii and enclosed masses in both Data Table 2 and Data Table 3, make a graph of \( M(<R) \) (on the Y axis) vs. \( R \) (on the X axis). Save your final graph as a png file.

**Question:** Upload your final png graph. (Submit a file with a maximum size of 1 MB. 5 points)

**Choose File** No file chosen

**Question:** Using your graph, estimate the mass of our galaxy within the sun's radius \( R = 8.1 \) kpc. (2 points)

\[ GM_{\odot} \]

**Question:** As we measured in Lab 6, our galaxy is about 34 kpc in diameter, so it is about 17 kpc in radius. Using your graph, estimate the mass of our galaxy within its visible-light radius \( R = 17 \) kpc. (2 points)

\[ GM_{\odot} \]

**Question:** Using your graph, estimate the mass of our galaxy within \( R = 61 \) kpc, the radius at which the Small Magellanic Cloud orbits? (2 points)
Question: Consequently, how much mass is between $R = 17$ kpc and $R = 61$ kpc? (2 points)

Question: Is the mass outside the visible part of our galaxy less or more than the mass inside the visible part of our galaxy? (2 points)

- less
- more

Question: The mass outside the visible part of our galaxy cannot be explained by the Large and Small Magellanic Clouds, whose masses are only $10 \ GM_{\text{sun}}$ and $7 \ GM_{\text{sun}}$, respectively. Within 61 kpc, is our galaxy mostly visible matter, like stars and gas, or mostly dark matter? (2 points)

- visible
- dark

Question: Research and discuss what the dark matter, at least in our galaxy, might be. (4 points)
